DETAILED ACTION

Claim Rejections - 35 USC § 103

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Claims 1-3 & 6-22 are rejected under 35 U.S.C. 103(a) as being unpatentable over Sokol et al. (USPN 6,254,703) in view of Dykes et al. (USPN 6,548,782) and Staver et al. (USPN 5,987,042).

Sokol et al. discloses a method and apparatus for quality control of laser shock processing. This includes measuring emissions and characteristics of the workpiece, using, for example, a radiometer or acoustic detection devices. Laser shock peening uses overlay(s) which maybe transparent (usually water or C, H, O type materials) or opaque (oil, tapes, paint and so forth). The radiometer (24) detects spectral emissions (22) and the acoustic detector (26) detects acoustic energy emissions (20). The radiometer measures a portion of the optical spectrum and is directed towards the workpiece (14) and in particular, that of the opaque overlay (10) such that radiometer (24) may measure the temperature of the workpiece and/or the plasma when a laser pulse irradiates them. Different types of radiometers may be used, such as UV, visible,

Art Unit: 1725

IR or narrower bands. These measurements yield real-time or in-process monitoring of the effectiveness of the laser shock peening.

Measurements may be implemented with a spectrometer or an array of fast photodiodes with narrow-band line filters selected to encompass the line of interest. Correctional or tables of the measurements may be generated. Thus a predetermined or desired range for a workpiece may be determined. In addition, one can use this method for producing uniform compressive residual stresses in a workpiece. (abstract, figure, col. 1, lines 18-30, col. 4, lines 20-67, col. 5, col. 6, lines 1-12, 47, col. 7, lines 10-15, 62-65, col. 8, lines 4-24, col. 9, lines 17-27)

Sokol et al. does not specifically teach the use of a controller or a laser with Q-switch and a clock signal.

Dykes et al. disclose a laser shock peening system, which uses an overlay. The laser beam (16) irradiates the workpiece (20) having an overlay (40) while a measurement device (15) measures the thickness of the both overlays (paint and water). The location of the measurement device may be located either near or outside the processing chamber. A control unit, such as a controller (28) is connected to the overlay, the workpiece, the measurement device, laser, positioning mechanism and so forth. Thus the system may be controlled real-time during the laser shock peening process. (abstract, figures, col. 4, lines 31-35, col. 6, col. 7, lines 25-67, col. 8, lines 10-53, col. 9, lines 34-47, col. 10, lines 45-51)

It would have been obvious to one of ordinary skill in the art at the time of the invention to use a controller, as taught by Dykes et al. in the Sokol et al. system

Art Unit: 1725

because the laser shock process may be controlled in-process or real-time and yield a product which meets desired parameters or predetermined ranges.

Staver et al. discloses a laser shocking processing system that improves workpiece surface characteristics by the formation of a surface layer in the material, which is in a state of compression. Typically, these systems use a transparent inertial confinement layer such as water. Laser pulses have to be controlled by a master clock trigger in order to optimize the exposure of the workpiece to laser peening. Actively controlling the relative timing of the laser pulse and the opening of the optical switch will result in a defined pulse that has a shape for effectively generating the desired mechanical stresses in the laser shock peened workpiece (target). The pulse generator controls the laser by actuating a high voltage relay, powered by a high voltage power supply that opens and closes the Q-switch in the laser oscillator. (abstract, figures, col. 1-2, col. 3, lines 22-50)

It would have been obvious to one of ordinary skill in the art at the time of the invention to use a laser with Q-switch and a clock signal, as taught by Staver et al. in the Sokol et al. system because well defined and accurately spaced laser shock peening pulses will effectively generate the desired mechanical stresses in the laser shock peening workpiece (target).

Art Unit: 1725

Allowable Subject Matter

Claims 4-5 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

The following is a statement of reasons for the indication of allowable subject matter: the claims as supported by the specification differs from the prior art in that it does not teach a system for laser shock peening having a logical AND gate coupled to the detector and pinhole aperture aligned with the detector.

Conclusion

The prior art made of record and not relied upon is considered pertinent to applicant's disclosure. See US PTO-892.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to M. Alexandra Elve whose telephone number is 571-272-1173. The examiner can normally be reached on 6:30-3:00 Monday to Friday.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Tom Dunn can be reached on 571-272-1171. The fax phone number for the organization where this application or proceeding is assigned is 703-872-9306.
